# Exposure Site Catalogue of atmospheric corrosion

field exposure sites in Europe

It is with great pleasure we launch this first edition of the Exposure Site Catalogue! Corrosion testing is an important part of corrosion work to estimate, assess, predict, and verify the performance and lifetimes of individual materials, systems, and components. This is an essential input for selection of appropriate corrosion protection systems and, in the end, to achieve sustainable products.

Exposure sites and outdoor exposure have always been a part of atmospheric corrosion research providing the "final answer", although at the cost of long exposure times. Individual exposure programs such as ISOCORRAG, MICAT and ICP Materials have resulted in collaborative networks of exposure sites. So far, however, there has been no collective effort to put together currently active sites in a comprehensive manner and across programs and nations. The information collected here is possible thanks to the work of all individual site managers listed as contact persons, efforts of members of Working Party 25 (WP25) Atmospheric Corrosion of the European Federation of Corrosion (EFC) and financial support of the EFC. With this Catalogue it is our hope that you can both get a general overview of what is available and be guided if you are looking for a particular environment with certain characteristics.

You will notice that there are several references to information contained in *ISO 9223 Corrosion* of metals and alloys – Corrosivity of atmospheres – Classification, determination, and estimation. It is recommended to be familiar with this standard, but if you are not. a brief recapitulation of its most important concepts is given in the explanatory notes.

Please do not hesitate to contact us if you are missing anything or have suggestions for improvement!

#### EXPLANATORY NOTES (more information can be found in ISO 9223<sup>1</sup>)

#### Corrosivity category or category of corrosivity of atmosphere

This is a standardized rating of the corrosivity of the atmosphere in relation to the one-year corrosion effect. Currently, six different categories are defined, C1 (very low corrosivity), C2 (low), C3 (medium), C4 (high), C5 (very high) and CX (extreme). The categories can be derived in different ways:

- Corrosivity determination based on corrosion rate measurement of standard specimens (recommended), normative based on exposure at test sites such as those in this Catalogue!
- Corrosivity estimation based on environmental information, normative based on dose-response functions including temperature, relative humidity sulphur dioxide level (deposition or concentration#), and chloride deposition.
- Corrosivity estimation based on environmental information, informative based on description of exposure conditions.

# In ISO 9223, SO<sub>2</sub> values determined by a deposition method and concentration values are considered equivalent and can be derived from each other by a constant factor with the physical interpretation as a constant deposition velocity. However, the deposition velocity can vary depending on the location, to a great extent depending on the wind speed.

#### **Categories of environment** and environmental parameters

Environmental parameters can be classified into different types:

- Climatic parameters including temperature, relative humidity, precipitation amount, etc. ٠
- Gaseous pollutants including SO<sub>2</sub>, NO<sub>x</sub>, O<sub>3</sub>, etc. •
- Particulate deposition including chloride deposition and other particles. •
- Characteristics of precipitation influenced by long-range and local effects including pH, sulfate, nitrate, and chloride content, etc.

The environment in general is also frequently characterized into different types such as rural, urban, marine, and industrial. It is however important to note that this description does not indicate the corrosivity category but only the type of the environment (and the types of pollutants that typically dominate in this environment). It is possible to find rural atmospheres having a high corrosivity category and urban sites having a low corrosivity category, even if the opposite is more frequent.

#### **Category of location**

This is conventionally defined as typical exposure conditions of a component or structure, for example, exposure in the open air, under shelter, in a closed space, etc. Some of the sites in this Catalogue provide exposure under shelter. It is however important to note that results obtained from one type of shelter are not easily extrapolated to other types of shelters due to the influence of microclimatic factors.

ISO 9223:2012. Corrosion of Metals and Alloys-Corrosivity of Atmospheres-Clasification, Determination and Estimation, 2<sup>nd</sup> ed.: International Organization for Standardization; Geneva. Switzerland, 2012

It consists of two separate fields. Field 1 is committed to accelerated, high salinity experiments (e.g." VDA 621-414 – like") and individual adapted exposure methods. Field 2, separated several meters from Nr.1 to avoid any cross contamination, is dedicated to classical atmospheric exposure. Being completely fenced and locating within the secured limits of the steel mill all fields are well protected against unauthorized influences and persons. Due to the vicinity of railroad tracks there are typical particle depositions (brake dust) present.

Site name Country, region Atmosphere Location (GPS) Altitude Address	Ostrava-Radvanice Czech Republic, Silesia Industrial 49.8084786N, 18.3437678E 260 m Podlesní 6, 716 00 Ostrava-Radv	ranice, Czech Re	public		
Description	The site is located in an industrial region of Silesia with steel industry and coal mining. The region is polluted mainly with $SO_2$ . The site is close to a steel producing facility. Due to the prevailing west winds, Ostrava-Radvanice is the most polluted part of the city of Ostrava. The site is located in a fenced garden.

Additional information	A full weather station is installed on the building roof (5 meters elevation) measuring data on air temperature, atmospheric pressure, relative humidity, solar irradiance, UV irradiance, rain rate, wind speed and direction, presence of wet film (leaf weatness) and sea water temperature; data are stored every 15 minutes. Chloride deposition is assessed by the wet candle method (ISO 9225). SO <sub>2</sub> and other pollutants are not directly monitored, but values from regional monitoring nearby stations are available. Two webcams are also present for the live evaluation of samples degradation and for the exposure area safety control. GEMS is included in the MARS Network - The European Network of Marine Research Institutes and Stations (http://www.marsnetwork.org), in Eurocean-Marine Research Infrastructures Database (http://www.eurocean.org ). A support CNR-IAS team usually assists partners, taking also care of logistic operations. In addition, it is also possible to perform static and dynamic (by boat) immersion tests in natural seawater in-field an in semi-field conditions.

## IT, Monte Cimone

Site name Country, region Atmosphere Location (GPS) Altitude	Ottavio Vittori Climate Observatory, Monte Cimone Italy, Northern Italian Apennines High UV 44.1933628N, 10.7010394E 2165 m				
Description	The Plateau Rosa Station (PRS) was installed upon a large snow-clad mountain plateau far from urban and polluted zones. PRS is one of the highest monitoring regional stations of the World Meteorological Organization GAW Programme. It is very often located above the planetary boundary layer, suitable for the background measurement of greenhouse gases and other environment background parameters. A meteorological station, managed by the Italian Meteorological Service (WMO code: 16052) is located at a horizontal distance of about one hundred meters from the PRS collecting, in real time, air temperature, relative humidity, pressure and wind (speed and direction) data. The measurement of the most important greenhouse gases (excluding water vapour), such as CO2, CH4, and O3, is regularly carried out. The PRS station is equipped with an electrical heating system and does not use any fossil fuel. A refuge and a cable car are located in the vicinity of the measuring station; both only operate during daylight hours and are open for about eight months a year. The climate at the Plateau Rosa station is typical of a continental alpine location, with relatively large diurnal and seasonal temperature variations of 6-8°C in a range between -15 and 4°C. Frequent atmospheric pressure variations and strong winds (generally > 4 m s-1) are documented. In the 1971–2008 period, wind speeds < 1 m s-1) occurred during about 17% of the measurements and winds from NE (about 25% of the events) prevailed.

Available space	Around 20 m <sup>2</sup> (can be expanded)						
Additional information	This test site was included in the National Corrosion Map elaborated in the early 90's. Chloride and SO <sub>2</sub> deposition rates were measured by the wet candle method and by the sulphur dioxide method, respectively (ISO 9225). Climatic data from the nearest weather station owned by the Portuguese Institute for Sea and Atmosphere (IPMA) at the time, 8 km distant, also on the shore. It is currently active, measuring data on air temperature, atmospheric pressure, relative humidity, solar irradiance, rainfall, wind speed and direction, which is available on request.

Available space	About 100 m <sup>2</sup> for placing test bench	nes				
Additional information	About 100 m² for placing test benches Monitoring of atmospheric parameters: air temperature, relative humidity, solar irradiance, precipitation, wind speed and direction, time of wetness, with data collection every 10 seconds and storage every 10 minutes. Chloride deposition rate is evaluated by the wet candle method and sulfur dioxide deposition rate on lead dioxide sulfation plates (ISO 9225). The evaluation of the sulfur dioxide content in the atmosphere using a sensor is under development with data collection and storage, similarly to other parameters. The annual global radiation similar to that of Florida, but with a different distribution throughout the year. The cycle of UV radiation at Lumiar / Lisbon Test Site is best suited to the European location then that recorded in Florida, being thus more relevant for many European countries, and consequently for manufacturers of coil coated placing their products in these countries. The average annual temperature, as well as the annual distribution of temperature, relative humidity and rainfall are also more significant for European countries. Materials usually exposed: reference panels of different materials/metals, samples with organic coating, absorbers and reflectors surfaces, thermal solar collectors, polymeric materials, natural materials (e.g. wood), etc. Costs: Cost depends of samples dimensions and exposure time. Cost upon request.
